# A new species of the genus *Theloderma* Tschudi, 1838 (Amphibia: Anura: Rhacophoridae) from Tay Nguyen Plateau, central Vietnam

Nikolay A. Poyarkov, Jr. 1,2,\*, Ivan I. Kropachev<sup>3</sup>, Svetlana S. Gogoleva<sup>4,5,6</sup>, Nikolai L. Orlov<sup>7</sup>

## **ABSTRACT**

A new species of small tree frog from a primary montane tropical forest of central Vietnam, Tay Nguyen Plateau, is described based on morphological, molecular, and acoustic evidence. The Golden Bug-Eved Frog, Theloderma auratum sp. nov., is distinguishable from its congeners and other small rhacophorid species based on a combination of the following morphological attributes: (1) bony ridges on head absent; (2) smooth skin completely lacking calcified warts or asperities; (3) pointed elongated tapering snout; (4) vocal opening in males absent; (5) vomerine teeth absent: (6) males of small body size (SVL 21.8-26.4 mm); (7) head longer than wide; ED/SVL ratio 13%-15%; ESL/SVL ratio 16%-20%; (8) small tympanum (TD/EL ratio 50%-60%) with few tiny tubercles; (9) supratympanic fold absent; (10) ventral surfaces completely smooth; (11) webbing between fingers absent; (12) outer and inner metacarpal tubercles present, supernumerary metacarpal tubercle single, medial, oval in shape; (13) toes half-webbed: I 2-21/4 II 11/2-23/4 III 2-31/4 IV 3-11/2 V; (14) inner metatarsal tubercle present, oval; outer metatarsal tubercle absent; (15) iris bicolored; (16) dorsal surfaces golden-yellow with sparse golden-orange speckling or reticulations and few small dark-brown spots; (17) lateral sides of head and body with wide dark reddish-brown to black lateral stripes, clearly

separated from lighter dorsal coloration by straight contrasting edge; (18) ventral surfaces of body, throat, and chest greyish-blue with indistinct brown confluent blotches; (19) upper eyelids with few (3–5) very small flat reddish superciliary tubercles; (20) limbs dorsally reddish-brown, ventrally brown with small bluish-white speckles. The new species is also distinct from all congeners in 12S rRNA to 16S rRNA mitochondrial DNA fragment sequences (uncorrected genetic distance P>8.9%). Advertisement call and tadpole morphology of the new species are described. Our molecular data showed *Theloderma auratum* **sp. nov.** to be a sister species of *Th. palliatum* from Langbian Plateau in southern Vietnam.

## INTRODUCTION

Rhacophoridae is a diverse family of largely arboreal tree frogs consisting of 414 currently recognized species in 18 genera (AmphibiaWeb, 2018; Che & Wang, 2016; Frost, 2018). Rhacophorids are distributed throughout Sub-Saharan Africa, China, Southern and Southeast Asia, Japan, Taiwan, the Philippines, and the Greater Sunda Islands (Frost, 2018). Species diagnostics and generic allocation within Rhacophoridae can be difficult, and molecular phylogenetic analyses are essential for correct taxonomic decisions (Jiang et al., 2016; Li et al., 2008, 2009; Orlov et al., 2012; Poyarkov et al., 2015; Rowley et al., 2011; Yu et al., 2009).

Frogs of the genus Theloderma Tschudi, 1838 are highly arboreal small- to large-sized rhacophorid frogs, which were traditionally grouped in one genus based on the presence of dorsal asperities or tuberculate dorsal skin (Liem, 1970; Rowley et al., 2011). However, recent studies have reported on several smooth species of rhacophorids that almost completely or totally lack dorsal asperities but are still assigned to Theloderma based on molecular data and reproductive biology (Nguyen et al., 2014; Orlov et al., 2012; Poyarkov et al., 2015). Thus, the taxonomy of Theloderma is in a current state of flux. Several studies have indicated a sister-clade relationship between Nyctixalus Boulenger, 1882 and Theloderma, with monophyly of the latter being poorly supported or not recovered (Dever et al., 2015; Dever, 2017; Rowley et al., 2011). Thus, Poyarkov et al. (2015) recognized Nyctixalus as a subgenus of Theloderma and assigned the Th. stellatum Taylor, 1962-Th. horridum (Boulenger, 1903) species group to the subgenus Stelladerma Poyarkov, Orlov, Moiseeva, Pawangkhanant, Ruangsuwan, Vassilieva, Galoyan, Nguyen & Gogoleva, 2015. Subsequent studies with larger taxon and gene sampling (Nguyen et al., 2015; Sivongxay et al., 2016) supported Nyctixalus as a sister clade with respect to Theloderma as well as monophyly of Theloderma and its subdivision into two highly divergent clades (corresponding to subgenera Theloderma and Stelladerma sensu Poyarkov et al., 2015). Theloderma moloch (Annandale, 1912), an enigmatic taxon whose phylogenetic position and assignment to Theloderma became uncertain due to sequences published by Li et al. (2009), was simultaneously rediscovered in Chinese and Indian regions of the Himalayas and shown to be a member of Theloderma s. str. (Hou et al., 2017; Lalronunga & Lalrinchhana, 2017; Li et al., 2016). In addition, Jiang et al. (2016) and Biju et al. (2016) concurrently demonstrated that sequences previously reported as "Th. moloch" by Li et al. (2009) actually corresponded to a distinct lineage of Rhacophoridae, representing new genus Nasutixalus Jiang, Yan, Wang & Che, 2016 (Jiang et al., 2016). The taxonomic position of Th. andersoni (Ahl, 1927) is also relatively unclear, with Hou et al. (2017) suggesting that this species might be a member of the genus Raorchestes Biju, Shouche, Dubois, Dutta & Bossuyt, 2010. Taking these reassignments and new species descriptions into consideration, a total of 25 species of Theloderma are recognized and distributed throughout Southeast Asia, from Assam in northeastern India to Myanmar, southern China and Indochina, the Malay Peninsula, and Sumatra and Borneo of the Greater Sunda Islands. New species in the genus continue to be discovered, with 13 described in the last 15 years alone (Frost, 2018).

During recent fieldwork in the montane forests of Tay Nguyen Plateau in central Vietnam, we encountered a small-sized rhacophorid species with a smooth dorsum. This tree frog was identified morphologically as a probable member of the genus Theloderma based on the presence of an intercalary cartilage between the terminal and penultimate phalanges of digits, a distinct tympanum, tips of the digits expanded into large disks bearing circummarginal grooves, absence of vomerine teeth, horizontal pupils, rounded canthus rostralis, terminal phalanx with a Y-shaped distal end, and the skin of the head not co-ossified to the skull (Liem, 1970; McLeod & Ahmad, 2007; Rowley et al., 2011). This species of frog was earlier reported by Orlov & Ananjeva (2007) and Orlov et al. (2012) as Theloderma laeve (Smith, 1924), a taxon described from the Langbian Plateau of southern Vietnam and originally assigned to the genus Philautus due to the presence of smooth skin on the dorsum and the lack of warts, tubercles, and asperities (Smith, 1924). Following examination of the holotype of Philautus laevis Smith, 1924, Poyarkov et al. (2015) demonstrated it to be conspecific to Theloderma bambusicolum Orlov, Poyarkov, Vassilieva, Ananjeva, Nguyen, Nguyen & Geissler, 2012 and confirmed its assignment to the genus Theloderma as Theloderma laeve (Smith, 1924). Consequently, the taxon previously identified as Th. laeve by Orlov et al. (2012) is not assigned to any currently recognized species of Theloderma. Close examination showed that this taxon can be easily distinguished from other known members of the genus Theloderma by a combination of several adult morphological characteristics. Molecular phylogenetic analysis of a 2 518-bp mtDNA fragment further indicated that this taxon is nested within the genus Theloderma with high support values and represents a sister species to Th. palliatum Rowley, Le, Hoang, Dau & Cao, 2011. In the present paper we discuss the phylogenetic position and taxonomic affiliation of this frog and describe it as a new species.

## **MATERIALS AND METHODS**

## Sample collection

Fieldwork was carried out in central Vietnam in May 2016 and May 2017. Specimens of *Theloderma* sp. were collected by hand in the montane evergreen tropical forests of Kon Ka Kinh National Park and Kon Chu Rang Nature Reserve, both in Gia Lai Province; and in Thac Nham Forest and Kon Plinh Forest, Mang Canh District, Kon Tum Province; Tay Nguyen Plateau, central Vietnam (Figure 1). Geographic coordinates and altitude were obtained using a Garmin GPSMAP 60CSx GPS receiver (USA) and recorded in datum WGS 84. Specimens were euthanized by 20% benzocaine and tissue samples (femoral muscles) for genetic analysis were collected and stored in 96% ethanol prior to specimen preservation. Specimens were subsequently preserved in 70% ethanol and deposited in the herpetological collection of the Zoological Museum of Moscow State University

(ZMMU) in Moscow, Russia. Comparative materials examined are stored in the herpetological collections of ZMMU and the Zoological Institute R.A.S. (ZISP) in St. Petersburg, Russia. A list of examined specimens is given in Appendix I.

# Morphological description

Specimens of Theloderma sp. were photographed in life and

after preservation. Sex was determined by direct observation of calls and by examination of the nuptial pads in collected males. Measurements were taken using a digital caliper under a light dissecting microscope to the nearest 0.01 mm, subsequently rounded to 0.1 mm. Statistical analyses were performed with Statistica 8.0 (StatSoft, Inc., 2007).

(type locality of Theloderma palliatum Rowley, Le, Hoang, Dau & Cao, 2011); 8: Bidoup Mt., Bidoup – Nui Ba N.P., Lam Dong Prov. Photos by Nikolay A. Poyarkov.

## Adult morphology

Morphometrics follow Orlov et al. (2012), Milto et al. (2013), and Poyarkov et al. (2015) and include the following 30 measurements: (1) SVL (snout-vent length); (2) A-G (axilla to groin, distance from posterior base of forelimb at its emergence from body to anterior base of hind limb at its emergence from body); (3) HW (head width at greatest cranial width); (4) HL (head length from rear of lower jaw to tip of the snout); (5) HD (head depth, greatest transverse depth of head, taken beyond interorbital region); (6) UEW (upper eyelid width, greatest width of upper eyelids); (7) IOD (interorbital distance); (8) ED (horizontal diameter of eye); (9) TD (horizontal diameter of tympanum); (10) ESL (tip of snout-eye distance); (11) IND (internarial distance between nostrils); (12) END (eye to nostril distance from anterior corner of eye to nostril); (13) TED (tympanum-eye distance from anterior edge of tympanum to posterior corner of eye); (14) NS (distance from nostril to tip of snout); (15) FLL (length of forelimb from tip of disk of finger III to axilla); (16) LAL (forearm length, from elbow to base of outer palmar tubercle); (17) ML (hand length from tip of third digit to base of outer palmar tubercle); (18) FFL (first finger length); (19) TFL (third finger length); (20) FTD (maximal diameter of disk of finger III); (21) NPL (nuptial pad length, measured for males only); (22) MKTe (length of external metacarpal tubercle); (23) HLL (length of hindlimb from tip of disk of toe IV to groin); (24) FL (femur length); (25) TL (tibia length); (26) FOT (length of hindlimb from tip of disk of toe IV to posterior edge of tibia); (27) FTL (first toe length); (28) FFTL (fourth toe length); (29) HTD (diameter of fourth toe tip, greatest diameter of disk on fourth toe); (30) MTTi (length of internal metatarsal tubercle). Skin texture, dorsal coloration, ventral coloration, and presence of supratympanic folds, circummarginal grooves, dorsolateral folds, vomerine teeth, hind limb and forelimb webbing, and dorsal, lateral, and ventral coloration were recorded. Webbing formula follows Savage & Heyer (1997).

Data and adult morphological characters chosen for comparison with other Theloderma species and allied taxa were taken from the following sources: Ahl (1927, 1931); Anderson (1879); Annandale (1912); Bain et al. (2009); Boulenger (1882, 1886, 1893, 1903); Bourret (1937, 1942); Chan & Ahmad (2009); Chan-ard (2003); Das et al. (2013); Das (2007); Dever et al. (2015); Dever (2017); Fei et al. (1990, 2009, 2010); Hou et al. (2017); Inger (1954, 1966); Lalronunga & Lalrinchhana (2017); Li et al. (2011, 2016); Liem (1970); Liu & Hu (1962); Manthey & Grossmann (1997); Mathew & Sen. (2010); McLeod & Ahmad (2007); Nguyen et al. (2014); Orlov & Ananjeva (2007); Orlov & Ho (2005); Orlov et al. (2006, 2010, 2012); Orlov (2007); Peters (1871); Poyarkov et al. (2015); Rowley et al. (2011); Sivongxay et al. (2016); Smith (1924, 1926, 1930, 1931); Stuart & Heatwole (2004); Taylor (1920, 1962); Von Tschudi (1838); Wolf (1936); Zhao & Adler (1993).

## Larval morphology

Morphometric data and abbreviations for larval characters follow Altig & McDiarmid (1999), Altig (2007), Grosjean (2001), and Hendrix et al. (2007). Labial tooth row formulae (LTRF)

follow Altig & McDiarmid (1999). Tadpoles were staged according to the tables of Gosner (1960). All measurements were taken on freshly preserved specimens. Tadpoles were euthanized with ethyl acetate and preserved in 70% ethanol. The following 17 measurements were taken: (1) BH (maximum body height); (2) BL (body length); (3) BW (maximum body width); (4) ED (maximum diameter of eye); (5) NP (naro-pupilar distance); (6) IND (internarial distance, measured between centers of narial apertures); (7) IOD (interorbital distance); (8) ODW (oral disk width); (9) RN (rostro-narial distance); (10) SS (distance from tip of snout to spiracle opening); (11) LF (maximum height of lower tail fin); (12) MTH (maximum tail height); (13) TAL (tail length); (14) TL (total length); (15) TMH (height of tail musculature at base); (16) TMW (width of tail musculature at base); (17) UF (maximum height of upper tail fin).

## DNA isolation, PCR, and sequencing

Total genomic DNA was extracted from the ethanol-preserved muscle tissues using standard phenol-chloroform extraction (Hillis et al., 1996). Total DNA concentration was estimated in 1  $\mu$ L using a NanoDrop 2000 (Thermo Scientific, USA), and consequently adjusted to 100 ng DNA/ $\mu$ L.

We amplified the mtDNA fragment consisting of partial sequences of 12S rRNA, tRNAval, and 16S rRNA mtDNA genes. These markers were chosen due to their successful use in studies of Rhacophorid taxonomic diversity (Bain et al., 2009; Dever et al., 2015; Li et al., 2008, 2009, 2013; Meegaskumbura et al., 2015; Nguyen et al., 2014, 2015; Poyarkov et al., 2015; Rowley et al., 2011; Wilkinson & Drewes, 2000; Wilkinson et al., 2002; Yu et al., 2007, 2008; and references therein). PCR was performed in 20-µL reactions using 50 ng of genomic DNA, 10 nmol of each primer, 15 nmol of each dNTP, 50 nmol additional MgCl<sub>2</sub>, Taq PCR buffer (10 mmol/L Tris-HCl, pH 8.3, 50 mmol/L KCI, 1.1 mmol/L MgCl<sub>2</sub>, and 0.01% gelatin), and 1 U of Taq DNA polymerase. Primers used in PCR and sequencing were obtained from previous studies (Hedges, 1994; Li et al., 2008, 2009; Wilkinson et al., 2002) and are summarized in Table 1. The PCR conditions for amplification of the 12S rRNA and 16S rRNA gene fragments followed those described in Poyarkov et al. (2015).

PCR products were visualized by agarose electrophoresis in the presence of ethidium bromide and consequently purified using 2  $\mu$ L from a 1:4 dilution of ExoSaplt (Amersham, UK) per 5  $\mu$ L of PCR product prior to cycle sequencing. Sequence data collection and visualization were performed on an ABI 3730xl automated sequencer (Applied Biosystems, USA) in Evrogen Inc., Moscow. The obtained sequences were aligned and deposited in GenBank under the accession numbers MG917762–MG917772 (Table 2).

## Phylogenetic analyses

Sequences of the 12S rRNA, tRNA<sup>val</sup>, and 16S rRNA mtDNA fragments from 135 Rhacophoridae specimens, including 122 representatives of *Theloderma* (ca. 27 species), and 13 sequences of outgroup members of Rhacophoridae (genera *Rhacophorus*, *Nasutixalus*, and *Nyctixalus*) were included in the final alignment with a total length of 2 518 bp.

Details on voucher specimens and GenBank accession Nos. used in phylogenetic analyses are summarized in Table 2. Nucleotide sequences were initially aligned using ClustalX 1.81

(Thompson et al., 1997) with default parameters, and then checked by eye in BioEdit 7.0.5.2 (Hall, 1999) and MEGA 7.0 (Kumar et al., 2016) and slightly adjusted.

-: Not available.

The dataset was divided into three partitions, 12S rRNA, tRNA<sup>val</sup>, and 16S rRNA, with the optimal evolutionary models then estimated using MODELTEST v.3.06 (Posada & Crandall, 1998). For the 12S and 16S rRNA partitions, the best-fitting model according to the Akaike information criterion (AIC) was the HKY+I+G model; whereas for the tRNA<sup>val</sup> partition, the Kimura 2-parameter model (+G+I) was selected as the one of best fit. Mean uncorrected genetic distances (*P*-distances) between sequences were determined with MEGA 7.0 (Kumar et al., 2016).

Matrilineal genealogy was inferred using Bayesian inference (BI) and maximum likelihood (ML) algorithms. The BI analyses were conducted in MrBayes 3.1.2 (Huelsenbeck & Ronquist, 2001; Ronquist & Huelsenbeck, 2003). Metropolis-coupled Markov chain Monte Carlo (MCMCMC) analyses were run with one cold chain and three heated chains for ten million generations and sampled every 1 000 generations. Five independent MCMCMC runs were performed and 1 000 trees were discarded as burn-in. Confidence in tree topology was tested by posterior probability (PP) for Bayesian inference (BI) trees (Huelsenbeck & Ronquist, 2001). Nodes with posterior probability values over 0.95 were a priori regarded as sufficiently resolved, whereas those between 0.95 and 0.90 were regarded as tendencies, and those below 0.90 were considered as unsupported.

The ML analyses were conducted using Treefinder (Jobb et al., 2004) and confidence in node topology was tested by non-parametric bootstrapping with 1 000 replicates (ML BS, see Felsenstein, 1985). We *a priori* regarded tree nodes with bootstrap (ML BS) values of 70% or greater and Bayesian posterior probabilities (BI PP) values over 0.95 as sufficiently resolved; ML BS values between 70% and 50% (BI PP between 0.95 and 0.90) were treated as tendencies and nodes with ML BS values below 50% (BI PP below 0.90) were regarded as unresolved (Felsenstein, 2004; Huelsenbeck & Hillis, 1993).

## Acoustic analyses

Advertisement calls of the *Theloderma* sp. were recorded in habitat in Kon Chu Rang Nature Reserve, Gia Lai Province, Tay Nguyen Plateau, Vietnam (N14 $^\circ$ 30'19.7", E108 $^\circ$ 32'30.0"; 950 m a.s.l.) on 26 May 2016 from 0224 h to 0300 h at an ambient temperature of 21.5  $^\circ$ C (temperature was measured at the calling site immediately after recording with a digital thermometer KTJ TA218A Digital LCD Thermometer-Hydrometer) using a portable digital audio

recorder Zoom h5 (ZOOM Corporation, Tokyo, Japan) in stereo mode with 48 kHz sampling frequency and 16-bit precision. In total, two recordings from two males (ZMMU A-5828 and A-5829) were made.

Calls were analyzed using Avisoft SASLab Pro software v.5.2.05 (Avisoft Bioacoustics, Germany). Before analysis, we reduced background noise using low-pass (up to 500 Hz) and high-pass filters (down to 7 kHz). All parameters were measured in the spectrogram window of Avisoft. Spectrograms were created under Hamming window, FFT-length 1 024 points, frame 75%, and overlap 87.5%. For figure spectrograms, we lowered the sampling rate to 22.05 kHz. Figure spectrograms were created under Hamming window, FFT-length 512 points, frame 100%, and overlap 50%. In total, we measured 214 *Theloderma* sp. calls.

We measured four temporal parameters (duration of each call and series and interval between successive calls and series) and three frequency parameters (initial and final fundamental frequency and frequency of maximum amplitude). We also calculated the call repetition rate (calls/s) by counting the number of calls within each series, minus one, and dividing that number by the series duration. All numeral parameters are given as means±*SE*, and the minimum and maximum values are given in parentheses (min–max).

## **RESULTS**

# Phylogenetic analyses Sequences and statistics

The final alignment contained 2 518 aligned characters, with 1 090 conserved sites and 1 395 variable sites, of which 1 170 were found to be parsimony-informative. The transition-transversion bias (R) was 2.372 (data given for ingroup only). Nucleotide frequencies were 30.10% (A), 20.18% (T/U), 27.40% (C), and 22.31% (G).

# Position of *Theloderma* sp. in matrilineal genealogy

The phylogenetic analyses results are presented in Figure 2. The ML and BI phylogenetic analyses resulted in essentially similar topologies. In general, the BI cladogram topology was consistent with results reported in previous work (Nguyen et al., 2015; Sivongxay et al., 2016), suggesting monophyly of the clade joining *Nyctixalus* and *Theloderma* (node support values 1.0/100, hereafter given for BI PP/ML BS, respectively) and monophyly of *Theloderma*, though only with moderate support (0.90/85).

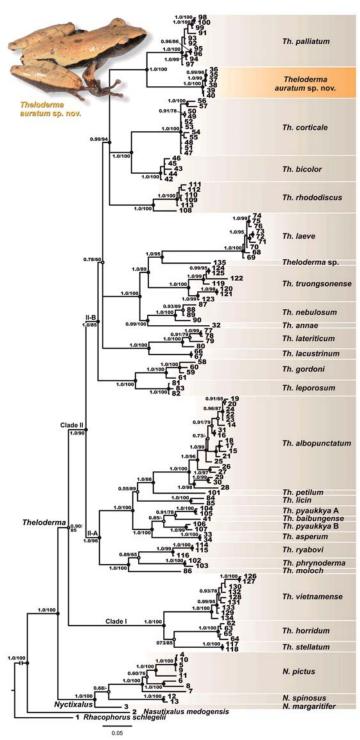

Figure 2 Bayesian inference dendrogram of Theloderma and its relatives derived from analysis of 2 518-bp length 12SrRNA - 16S rRNA mtDNA gene fragments

Numbers of specimens (No. 1–135), corresponding voucher specimen information and GenBank accession numbers are given in Table 2. BI PP/ML BS support values are given only for resolved nodes. Highly supported nodes are marked with black circles (PP node support >0.95), grey circles indicate moderately supported nodes (0.90<PP<0.95), and white circles indicate unsupported nodes (PP<0.90). Photo by Nikolay A. Poyarkov.

The genus *Theloderma* was divided into two strongly-supported major clades: Clade I (1.0/100), joining *Th. stellatum*, *Th. Horridum*, and *Th. vietnamense* Poyarkov, Orlov, Moiseeva, Pawangkhanant, Ruangsuwan, Vassilieva, Galoyan, Nguyen & Gogoleva, 2015 (corresponding to the subgenus *Stelladerma*) and Clade II (1.0/90), joining all remaining species of the genus (subgenus *Theloderma* s.str.) (Figure 2). Clade II was further subdivided into subclade II-A (Sundaland, Indochina, eastern Himalayas, southern China; 1.0/96) and subclade II-B (Indochinese species; 1.0/85).

Subclade II-A joined two species groups: the Th. moloch group consisting of large-sized warty species from Indochina and the eastern Himalayas (i.e., Th. moloch, Th. phrynoderma (Ahl, 1927), and Th. ryabovi Orlov, Dutta, Ghate & Kent, 2006; 1.0/100)) and the Th. asperum group consisting of medium to small-sized species with contrasting black and white dorsal coloration (i.e., Th. asperum (Boulenger, 1886), Th. pyaukkya Dever, 2017, Th. baibungense (Jiang, Fei & Huang, 2009), Th. licin McLeod & Ahmad, 2007, Th. petilum (Stuart & Heatwole, 2004), and Th. albopunctatum (Liu & Hu, 1962); 1.0/100)). Our data strongly suggested paraphyly of Th. pyaukkya with respect to Th. baibungense, with the former subdivided into two divergent lineages from northern and central Myanmar (A and B, see Figure 2) with poorly resolved genealogical relationships. Furthermore, Th. albopunctatum represents a species complex with at least four divergent lineages with unclear geographic structuring (see Figure 2, Table 2).

Phylogenetic relationships within subclade II-B were essentially unresolved (Figure 2), though the following species groups were supported: Th. leporosum group (joining Th. leporosum Tschudi, 1838 and Th. gordoni Taylor, 1962; 1.0/100), Th. lateriticum group (including Th. lateriticum Bain, Nguyen & Doan, 2009 and Th. lacustrinum Sivongxay, Davankham, Phimmachak, Phoumixay & Stuart, 2016; 1.0/100), Th. laeve group (including Th. laeve, Th. truongsonense (Orlov & Ho, 2005), Th. nebulosum Rowley, Le, Hoang, Dau & Cao, 2011, and Th. annae Nguyen, Pham, Nguyen, Ngo & Ziegler, 2016; 1.0/100), and Th. corticale group (joining Th. corticale (Boulenger, 1903), Th. bicolor (Bourret, 1937), Th. rhododiscus (Liu & Hu, 1962), Th. palliatum, and Theloderma sp. from the Tay Nguyen Plateau; 0.99/94). A single specimen (VNMN 4403) from Gia Lai Province identified as Th. laeve by Nguyen et al. (2015) was grouped with samples of Th. laeve s. str. from southern Vietnam with high support (1.0/95) but represented a clearly distinct genealogical lineage and was identified as Theloderma sp. in the present paper.

The *Theloderma* sp. from Tay Nguyen Plateau was recovered as a sister species of *Th. palliatum*, which inhabits the montane forests of Langbian Plateau, with strong node support (1.0/100) (Figure 2); however, no clear structuring was observed within the *Theloderma* sp. clade.

# Sequence divergence

The uncorrected *P*-distances among and within the studied 2 518-bp mtDNA fragments for the examined *Theloderma* species are shown in Table 3 (data given for the ingroup only). The interspecific uncorrected genetic *P*-distances between the

Theloderma sp. from Tay Nguyen Plateau and other congeners varied from 8.9% (between Theloderma sp. and sister species Th. palliatum) to 17.9% (between Theloderma sp. and Th. laeve) (Table 3). This degree of pairwise divergence was high, notably greater than the genetic divergence thresholds representing species level differentiation in frogs (Vences et al., 2005a, 2005b; Vieites et al., 2009).

## **Taxonomy**

Based on the phylogenetic analyses of the 2 518-bp length 12S rRNA and 16S rRNA mtDNA fragment sequences, the examined specimens of *Theloderma* sp. from Tay Nguyen Plateau in central Vietnam represented a highly divergent mtDNA lineage, clearly distinct from all other *Theloderma* species for which comparable mtDNA sequences are available (Figure 2), and a sister species of *Th. palliatum* from Langbian Plateau of southern Vietnam. The observed differences in mtDNA sequences were congruent with evidence from the diagnostic morphological characters (see "Comparisons"). These results support our hypothesis that the small-sized "smooth" *Theloderma* sp. from Tay Nguyen Plateau represents a previously unknown species, which we describe herein.

## Theloderma auratum sp. nov.

Tables 4, 5; Figures 3-8.

**Holotype**: ZMMU A-5828 (field number NAP-06351), adult male from montane evergreen tropical forest in Kon Chu Rang Nature Reserve, Gia Lai Province, Tay Nguyen Plateau, central Vietnam (N14°30′19.7′′, E108°32′30.0′′; elevation 950 m a.s.l.), collected when calling from bush leaves ca. 40 cm above the ground on 26 May 2016 at 0235 h by Nikolay A. Poyarkov.

Paratypes: ZMMU A-5829 (field number NAP-06352) and ZMMU A-5830 (field number NAP-06353), two adult males from the same locality and with the same collection information as the holotype; ZMMU A-5831 (field number NAP-06354), adult male from montane evergreen tropical forest in Kon Ka Kinh National Park, Gia Lai Province, Tay Nguyen Plateau, central Vietnam (N14°13'02.8", E108°19'53.3"; elevation 1 420 m a.s.l.), collected ca. 1 m above the ground from vegetation on 12 May 2016 at 2300 h by Nikolay A. Poyarkov; ZMMU A-5832 (field number NAP-06402), adult male from montane evergreen tropical forest in Thac Nham Forest, Kon Plong District, Mang Canh Commune, Kon Tum Province, Tay Nguyen Plateau, Vietnam (N14°43'32.4", E108°18'04.5"; elevation 1 230 m a.s.l.), collected ca. 30 cm above the ground from vegetation on 5 June 2016 at 2000 h by Nikolay A. Poyarkov.

Referred specimens: ZISP 13422–13426, five tadpoles (Gosner stages 29–36) born and reared in captive laboratory conditions from adult specimens collected from montane evergreen tropical forest in Kon Plinh Village, Kon Plong District, Kon Tum Province, Tay Nguyen Plateau, Vietnam; elevation ca. 1 000 m a.s.l.) in June 2014 by Ivan I. Kropachev and Nikolai L. Orlov.

Not available.

Diagnosis: The new species was assigned to the genus Theloderma by its (1) distinct tympanum, (2) terminal phalanx with Y-shaped distal end, (3) intercalary cartilage between terminal and penultimate phalanges of digits, (4) tips of digits expanded into large disks bearing circummarginal grooves, (5) head skin not co-ossified to skull (Liem, 1970; Nguyen et al., 2015; Poyarkov et al., 2015; Rowley et al., 2011), and molecular data (Figure 2). Theloderma auratum sp. nov. is distinguished from all other Theloderma by a combination of the following morphological attributes: (1) absence of bony ridges from canthus rostralis to occiput; (2) completely smooth skin on dorsum lacking calcified warts or asperities; (3) pointed elongated tapering snout with distinct rounded canthus rostralis, nostrils dorsolateral, not protuberant; (4) vocal opening in males absent; (5) vomerine teeth absent; (6) small body size in males (SVL 21.8-26.4 mm); (7) head longer than wide, head width to head length ratio 78%-84%; eye diameter to SVL ratio 13%-15%; snout length to SVL ratio 16%-20%; (8) comparatively small tympanum: tympanum diameter half of eye diameter (TD/EL ratio 50%-60%), tympanum with few tiny tubercles; (9) supratympanic fold absent; (10) ventral surfaces completely smooth; (11) webbing between fingers absent; (12) external and internal metacarpal tubercles present, supernumerary metacarpal tubercle single, medial, and oval in shape; (13) toes half-webbed, toe-webbing formula: I  $2-2\frac{1}{4}$  II  $1\frac{1}{2}-2\frac{3}{4}$  III  $2-3\frac{1}{4}$  IV  $3-1\frac{1}{2}$  V; (14) inner metatarsal tubercle present, oval; outer metatarsal tubercle absent; (15) iris bicolored, golden-orange dorsally, black with copper-red flecks ventrally with a wide black longitudinal stripe running medially, incorporating black pupil; (16) dorsal surfaces golden-yellow with sparse golden-orange speckling or reticulations and few small dark-brown spots (usually located at mid-dorsum, on upper eyelids, snout tip, and sacral area); (17) lateral sides of head and body with wide dark reddish-brown to black lateral stripes, clearly separated from lighter dorsal coloration by straight contrasting edge; (18) ventral surfaces of body, throat, and chest greyish-blue with indistinct brown confluent blotches; (19) upper eyelids with few (3-5) very small flat reddish superciliary tubercles; (20) limbs

dorsally reddish-brown, ventrally brown with small bluish-white speckles.

The new species is also markedly distinct from all congeners for which comparable sequences of the 2 518-bp length 12S rRNA to 16S rRNA mitochondrial DNA fragments are available (uncorrected genetic distance *P*>8.9%).

**Description of holotype**: Small-sized rhacophorid frog specimen in a good state of preservation; body slender, dorsoventrally compressed (Figure 3). Skin on ventral surface of left femur of holotype medially dissected 5 mm, with femoral muscles (partial) removed for molecular genetic analyses. Measurements of holotype are given in Table 4 (in mm).

Head: Head much longer than wide (HW/HL 83%), quite deep (HD/HL 42%), moderately flattened; dorsally smooth with skin not co-ossified to skull, lacking calcified warts, asperities, or sculpturing; snout long (ESL/HL 45%) and tapering, snout tip pointed in dorsal view (Figure 3A), rounded in profile (Figure 3D), snout notably projecting beyond margin of lower jaw (Figure 3D); nostril ovoid, not protuberant (Figure 3D), oriented dorsolaterally, located much closer to tip of snout than to eye (END/ESL 69%) (Figure 3D); canthus rostralis distinct, rounded; loreal region slightly concave; eyes large (ED/HL 36%), eye diameter less than snout length (ED/ESL 78%), notably protuberant in dorsal view (Figure 3A) and profile (Figure 3D), pupil horizontal, ovoid (Figure 3D; Figure 4); tympanum distinct and rounded, with vertical tympanum diameter equal to horizontal (TD) diameter (ratio 1.0); tympanic rim distinct, slightly elevated above skin of temporal region (Figure 3D), tympanum comparatively small comprising half of eye diameter (TD/ED 53%), located close to eye (TED/ED 22%); pineal ocellus absent; vomerine teeth absent; choanae ovoid, almost hidden under margins of mouth roof; vocal sac openings not discernable; tongue wide, spatulate, attached anteriorly with free posterior end, with no distinct notch at posterior end; supratympanic fold indistinct, smooth (Figure 3D. Figure 4).

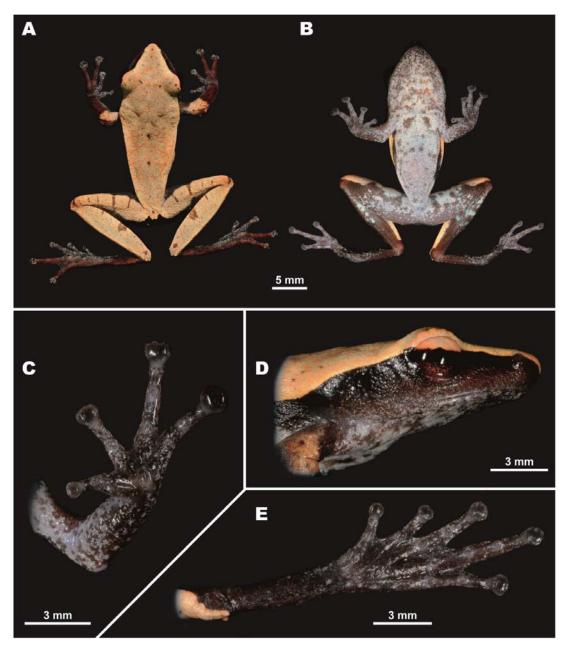

Figure 3 Male holotype of Theloderma auratum sp. nov. (ZMMU A-5828) in life (ex situ)

A: Dorsal view; B: Ventral view; C: Volar view of left hand; D: Lateral view of head; E: Plantar view of left foot. Photos by Nikolay A. Poyarkov.

Forelimbs: Forelimbs thin, slender; relative finger lengths: I<II<IV<III; tips of all fingers with well-developed disks with distinct circummarginal grooves (Figure 3C), disks two times wider than finger widths (third finger disk width (FTD) 205% of third finger width at penultimate phalanx), disks rounded to slightly trapezoid, slightly expanded transversally, third finger disk width 125% of third finger disk length; third finger disk width (FTD) 72% of tympanum diameter (TD); dermal fringing

on fingers not developed (Figure 3C); finger webbing absent; subarticular tubercles rather large, rounded, slightly protruding, distinct on all fingers, finger subarticular formula: I (1), II (1), III (2), IV (2); supernumerary metacarpal (palmar) tubercle single, medial, and ovoid; nuptial pad present, ovoid, elongated, covering prepollex area, comprising 46% of finger I length; two metacarpal tubercles present, inner metacarpal small and rounded, outer metacarpal tubercle flattened (Figure 3C).

Figure 4 Dorsolateral view of male holotype of Theloderma auratum sp. nov. (ZMMU A-5828) in life (in situ) (Photo by Nikolay A. Poyarkov)

Hindlimbs: Hindlimbs slender, relatively long, heels overlap when legs are at right angles to body (Figure 3A), tibiotarsal articulations reach well beyond tip of snout; tibia slightly over half of snout-vent length (TL/SVL ratio 55%); dermal ridge along outer side of tibia or tarsal fold absent; toes half-webbed. toe-webbing formula: I 2-21/4 II 11/2-23/4 III 2-31/4 IV 3-11/2 V; weak dermal fringes reaching to disks of all toes. Tips of toes bearing small disks with distinct circummarginal and transverse grooves; disks rounded, notably smaller than those of fingers (HTD/FTD ratio 91%); fourth toe disk width (HTD) 105% of fourth toe disk length; relative toe lengths: I<II<V<III<IV; round, clearly distinct protuberant subarticular tubercles on all toes. toe subarticular formula: I (1), II (1), III (2), IV (3), V (2); inner metatarsal tubercle well pronounced and notably protuberant, oval-shaped, 2.1 times longer than wide, outer metatarsal tubercle or supernumerary tubercles absent (Figure 3E).

Skin texture and skin glands: Dorsal skin smooth, with numerous small flat tubercles irregularly scattered on dorsal surfaces of head and body, forming weak reticulate pattern in sacral area (Figure 3A), lateral surfaces of head and body completely smooth; tympanum with few tiny evenly scattered tubercles; upper eyelids with few (3–5) very small flat reddish superciliary tubercles (Figure 3D); calcified asperities and warts on dorsum absent; area above insertion of forelimbs, and lateral sides of belly smooth; supratympanic and dorsolateral folds absent; dorsal surface of limbs weakly shagreened, ventral sides of limbs smooth; throat and chest smooth, belly and ventral surface of thigh smooth; dermal appendage at vent, dermal fringes and dermal tibiotarsal projections absent.

Color of holotype in life: Background of dorsal surface of head,

body, forearms, thighs, and shanks uniform golden-yellow with numerous tiny flat golden-orange tubercles on dorsal surfaces and supraciliary tubercles, getting somewhat denser posteriorly and forming weak reticulations in sacral area (Figure 3A; Figure 4). Small dark-brown spots of irregular shape located on dorsal surface of snout between nostrils, upper eyelids (two small spots on left and four spots on right upper eyelid), two spots on orbit margins between eyes, few small brown flecks in scapular area, two larger brown spots on mid-dorsal line (one in middle of dorsum, one in sacral area) and a single small spot above cloaca (Figure 3A). Elbows dorsally dark orange-brown. Four dark transverse dark-brown lines on dorsal surface of each thigh, orange-brown spot on each knee; on shanks a single short brown line at proximal end, larger light-brown blotch medially and smaller brown spot at distal end near tibiotarsal joint (Figure 3A).

Lateral sides of head and body with wide dark reddish-brown to black lateral stripes, clearly separated from lighter dorsal coloration by straight contrast edge, running from snout tip along canthus rostralis to anterior eye corner, then from posterior eye corner above tympanum and posteriorly to groin; dorsal edge of wide dark lateral stripe sharp and straight until groin, which shows very shallow dark inguinal loop with rounded edges. Tympanum uniformly dark-brown with no markings; tympanal area ventrally reddish-brown, dorsally black, sharply edged from light golden-yellow supratympanic area (Figure 3D).

Background of dorsal surfaces of arms, hands, and feet reddish-brown, with dense bluish-white to turquoise speckles, which spread to fingers and toes (Figure 3A); disks on digits dorsally brownish with dense whitish marbling, ventrally grey. Ventral surfaces of body, including belly and chest greyish-blue

with indistinct brown confluent blotches, getting smaller and denser anteriorly, forming dense brownish pattern on throat (Figure 3B). Two oblique brownish spots in chest area. Ventral surfaces of forelimbs grey with whitish speckling (Figure 3B, C). Ventral surfaces of hindlimbs reddish-brown with large bluish to turquoise blotches on groin, femur, and medial part of shank (Figure 3B). Throat, chest, and ventral surfaces of thighs with small bluish-white speckles.

Pupil horizontal, oval-shaped; iris bicolored, golden-orange dorsally, copper-red with thick black intervening ventrally; with wide black longitudinal stripe running medially, incorporating black pupil (Figure 3D).

Color of holotype in preservative: After preservation in ethanol for two years, coloration pattern of holotype resembles that observed in life; however, yellowish and reddish tints faded completely, turning beige-grey, brownish-black patterns on lateral surfaces appeared brownish-grey; ventral coloration lost purple and bluish tints and looked beige-grey with brown spots.

Variation: All individuals in type series were very similar in morphology, body proportions, and body coloration; measurements of type series are shown in Table 4 and

representative photographs showing variation in dorsal and ventral coloration of four male paratypes in life are given in Figure 5 and Figure 6. All specimens show certain variation in number and position of small dark-brown spots on dorsum (Figure 5A, Figure 6) and ventral pattern, including size of two oblique brownish spots in chest area (Figure 5B). Coloration of Theloderma auratum sp. nov. showed slight variation in response to diel period and microhabitat conditions. In life, coloration of dorsum was somewhat lighter nocturnally than during daytime, with dorsal surfaces looking light-beige to cream. Variation in color related to diel period, stress, and other conditions has been reported for other species of Theloderma (McLeod & Ahmad, 2007; Rowley et al., 2011).

Tadpole description: Description of larval morphology was based on five tadpoles (Gosner stages 29-36) (ZISP 13422-13426) (see Referred specimens for details). Identification of tadpoles was confirmed by 16S rRNA partial sequencing (see Table 2). The main morphometric parameters of the tadpoles are given in Table 5. Ontogenetic stages of Theloderma auratum sp. nov. are shown in Figure 7. Details of tadpole morphology are presented in Figure 8.

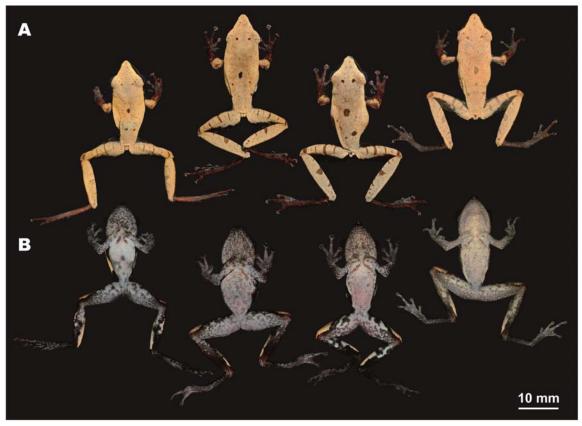

Figure 5 Male paratypes of Theloderma auratum sp. nov. in life in dorsal (A) and ventral (B) views (ex situ) From left to right: A-5831, A-5829, A-5830, and A-5832. Scale bar, 10 mm. Photos by Nikolay A. Poyarkov.

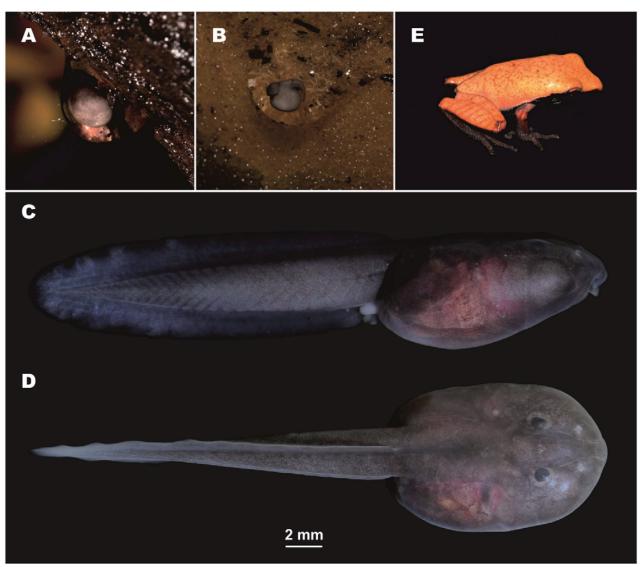

Figure 7 Ontogenetic stages of Theloderma auratum sp. nov. in life (ex situ)

A: Freshly laid egg; B: Developing embryo; C: Tadpole (Gosner stage 31), lateral view; D: Tadpole (Gosner stage 31), dorsal view; E: Metamorph. Photos A-B and E by Ivan I. Kropachev; photos C-D by Nikolay A. Poyarkov.

External morphology: Body oval, wider than high, body height 71%-78% of body width. Body longer than wide: body width 66%-74% of body length. Snout blunt, rounded. Tail more than two times longer than body, body length 55%-65% of tail length (Figure 7A, B); 23-28 myotomes discernable in lateral view. Nostrils rounded, oriented anterodorsally, located almost at same distance to snout as to eye (RN/NP ratio 71%-105%). Internarial distance (IND) 56%-77% of interorbital distance (IOD). Eyes with dorsal orientation. Eye diameter (ED) 9%-18% of body length (BL). Eye-nostril distance (END) larger than eye diameter (ED). Spiracle single, sinistral, located closer to posterior portion of body, directed laterally. Distance from tip of snout to spiracle opening 67%-75% times body length. Vent tube in medial position, with aperture located on same line as margin of ventral tail fin. Height of tail musculature at highest portion 58%-74% of tail height and 50%-57% of maximum body height. Maximum height of dorsal tail fin 34%-42% of maximum tail height. Ventral tail fin same height as dorsal tail fin; maximum height of lower tail fin 35%-46% of maximum tail height. Ventral and dorsal tail fins start roughly at level of vent. Dorsal and ventral tail fins slightly higher in posterior one third of tail length; tail tip gently rounded (Figure 7C; Figure 8A).

Oral disk: Mouth with ventral orientation (Figure 8C), oral disk wide, elliptical, width 38%-44% of body width. Lower labium fringed with double row of finger-shaped papillae (Figure 8D).

Submarginal papillae located laterally of upper and lower labium. Number of marginal papillae in one row 80-85. LTRF: 5(3-5)/3. Number of keratodonts 24-28 on 1 mm. Lower sheath "V"-shaped; upper sheath "U"-shaped, both with distinctly serrated edges (Figure 8D).

Coloration in life: Body strongly pigmented: dorsally and ventrally uniformly dark-grey (Figure 7C, D). In dorsal view, eyes not totally visible on strongly pigmentated background (Figure 7C). Iris black. Spiracle slightly pigmented. Dorsal and ventral tail fins translucent at edges with greyish coloration, much lighter than on body.

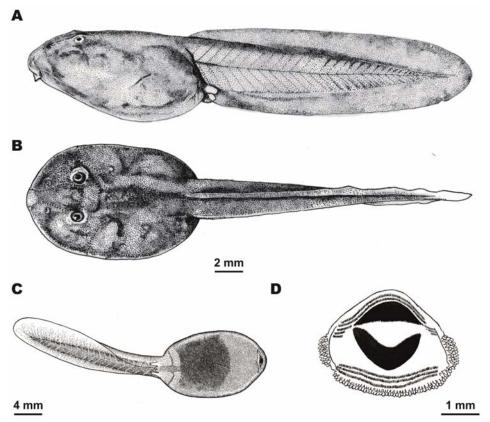

Figure 8 Tadpole morphology of *Theloderma auratum* sp. nov. (Gosner stage 31)

A: Lateral view; B: Dorsal view; C: Ventral view; D: Oral disk. Figures A-B by Valentina D. Kretova, Figures C-D by Ivan I. Kropachev.

Coloration in preservative: In ethanol, all parts of tadpoles were less intensively pigmented and turned greyish. preservation, myotomes of tail muscles were more discernable than in life.

Advertisement call: Advertisement calls of Theloderma auratum sp. nov. were uttered in a series of 14.27±1.31 (7-21, n=15) tonal calls (Figure 9), resembling an orthopteran call to the human ear. Series duration varied from 3.04 s to 11.34 s (7.88 $\pm$ 0.62 s, n=15) and the interval between successive series comprised  $21.61\pm2.57$  s (12.16-44.4 s, n=13). Call duration varied from 30 ms to 75 ms (61 $\pm$ 0.5 ms, n=214) and inter-call interval varied from 411 ms to 842 ms ( $529\pm6.76$ ms, n=199) usually decreasing gradually from the beginning to end of the series (Figure 9). Call repetition rate within

the series was  $1.68\pm0.03$  calls/s (1.53-1.98 calls/s, n=15). Initial fundamental frequency was 2 777±3 Hz (2 570-2 900 Hz, n=214) and final fundamental frequency was 2 856 $\pm$ 4 Hz (2 710-3 090 Hz, n=214). The initial and final fundamental frequencies also represented the minimum and maximum fundamental frequencies, respectively. Frequency modulation was usually expressed in the weak lift of fundamental frequency during the whole call. The presence of harmonics varied between/within recordings and mostly depended on recording quality (e.g., sensitivity of recording equipment, distance from vocalizing animal, signal volume, and background noise). Calls from the highest quality recording contained poorly visible second harmonics (Figure 9). The maximum amplitude frequency varied from 2 760 to 2 950 Hz (2 829 $\pm$ 2 Hz, n=214) and coincided with the fundamental frequency.

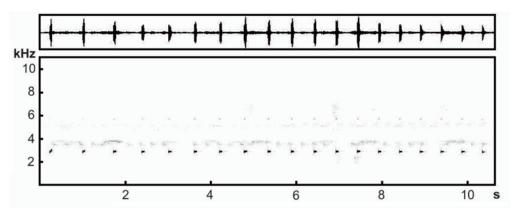

Figure 9 Oscillograms (top) and sonograms (bottom) of male advertisement calls of holotype of *Theloderma auratum* sp. nov. (ZMMU A-5828), recorded at 21.5 °C (Kon Chu Rang Nature Reserve, Gia Lai Province, Tay Nguyen Plateau, central Vietnam)

Position in mtDNA genealogy and sequence divergence: According to our mtDNA data, *Theloderma auratum* sp. nov. belongs to the subgenus *Theloderma* s. str. (Poyarkov et al., 2015), and is reconstructed as a sister species of *Th. palliatum* (Figure 2, clade II-B). Uncorrected genetic *P*-distances between *Theloderma auratum* sp. nov. 12S rRNA and 16S rRNA sequences and all homologous sequences of congeners included in our analyses varied from 8.9% (with sister species *Th. palliatum*) to 17.9% (with *Th. laeve*) (see Table 3). This value is higher than that observed between several currently recognized species of *Theloderma* (Table 3).

**Distribution and biogeography**: The known distributions of *Theloderma auratum* **sp. nov.** and its sister species *Th. palliatum* are shown in Figure 1. To date, the new species is known from montane evergreen tropical forests of Tay Nguyen Plateau in the central Annamite (Truong Son) Mountains, and has been recorded in Gia Lai, Kon Tum, and Thua Thien-Hue provinces. It is anticipated that *Theloderma auratum* **sp. nov.** 

also occurs in the adjacent montane forests of Tay Nguyen Plateau; in particular, records from Quang Nam Province of Vietnam and Xekong Province of Laos are anticipated.

Natural history notes: Our knowledge on the biology of *Theloderma auratum* sp. nov. is scarce. The new species was recorded in primary polydominant tropical montane evergreen forests of Tay Nguyen Plateau at elevations ranging from 800 to 1 400 m a.s.l.. Animals were recorded only in patches of primary undisturbed forest with complete multi-layered canopy and heavy undergrowth, suggesting the new species is a strict forest-dwelling specialist. At the type locality in Kon Chu Rang Nature Reserve (Gia Lai Province), the forest where the new species was recorded is dominated by large trees of the families Podocarpaceae (*Dacrydium elatum, Dacrycarpus imbricatus*), Magnoliaceae, Burseraceae (*Canarium* sp.), Myrtaceae (*Syzygium* sp.), Hamamelidaceae (*Simingtonia* sp.), Lauraceae (*Litsia* sp.), Rhodoliaceae (*Rhodolia* sp.), Fagaceae, Sterculiaceae (*Scaphium* sp.) (Figure 10).

Figure 10 Habitat of *Theloderma auratum* sp. nov. at type locality; montane tropical forest in Kon Chu Rang Nature Reserve, Gia Lai Province, Tay Nguyen Plateau, central Vietnam (Photo by Alina V. Alexandrova)

Theloderma auratum sp. nov. is a very secretive species with apparently nocturnal activity. Animals were usually encountered at night (between 1900 h and 0300 h) after or during heavy rain; males were recorded when calling from shrubs or small trees ca. 20–90 cm above the ground. Diet of the new species remains unknown. In Kon Plong District, Kon Tum Province, both males and females were observed at an elevation of 1 000 m a.s.l. when sitting on leaves of shrubs at 40–50 cm from the ground; animals were active at an air temperature of 20–22 ℃ and 100% humidity.

Other species of anurans recorded syntopically with the new species at the type locality included Ingerophrynus galeatus (Günther, 1864), Kurixalus banaensis (Bourret, 1939), Rhacophorus annamensis Smith, 1924, Rhacophorus rhodopus Liu & Hu, 1960, Rh. robertingeri Orlov, Poyarkov, Vassilieva, Ananjeva, Nguyen, Nguyen & Geissler, 2012, Polypedates mutus (Smith, 1940), Rana johnsi Smith, 1921, Sylvirana nigrovittata (Blyth, 1856), Microhyla pulverata Bain & Nguyen, 2004, and Occidozyga vittata (Andersson, 1942). In Kon Ka Kinh National Park (Gia Lai Province), the new species was recorded in sympatry with three other Theloderma species, including Th. albopunctatum, Th. vietnamense, and Th. truongsonense, with the latter species sharing the same biotopes as Theloderma auratum sp. nov. In Thac Nham Forest (Kon Plong Province), the new species was recorded in sympatry with Th. albopunctatum, Th. gordoni, and Th. ryabovi.

Reproductive biology: Reproduction of the new species was observed under laboratory conditions. In terrarium, clutches of Theloderma auratum sp. nov. were found on the under-surface of snags (Figure 7) and were usually deposited 2-4 cm above the surface of the water. A clutch consisted of one or two, rarely three eggs, enveloped in slimy transparent external egg-capsules (see Figure 7A, B). Duration of embryonic development comprised 10-12 d at ambient air temperatures of 22-23 °C. Tadpoles were fed on dry fish food and started active feeding 2-3 d after hatching. Duration of larval development from hatching to the end of metamorphosis was about 2.5 months. At metamorphosis, the main aspects of coloration and dorsal pattern corresponded to that of the adults, except the dorsal coloration pattern: metamorphs had a more intensive orange dorsum with orange reticulate pattern (Figure 7E), which disappeared with age.

Comparisons: Theloderma auratum sp. nov. is easily distinguished from most species of the genus Theloderma by a combination of the following morphological attributes: (1) small to medium body size (SVL 21.8–26.4 mm); (2) absence of vomerine teeth; (3) smooth skin on dorsum with dorsal warts or asperities absent, (4) long obtuse snout with pointed snout tip, ESL/SVL ratio 16%–20%; (5) uniform golden-yellow dorsal coloration with weak golden-orange speckling and reticulations; (6) dark reddish-brown to black lateral stripes, separated from dorsal light coloration by sharp edge, forming very weak and shallow inguinal loop; and (7) bicolored iris, golden-orange dorsally, copper-red with thick black intervening ventrally, with a wide black longitudinal

medial stripe.

The small body size, absence of vomerine teeth, and smooth dorsal skin lacking asperities or warts distinguishes *Theloderma auratum* **sp. nov.** from the large-sized *Theloderma* species: *Th. bicolor* (Bourret, 1937), *Th. corticale* (Boulenger, 1903), *Th. gordoni* Taylor, 1962, *Th. leporosum* Tschudi, 1838, *Th. moloch* (Annandale, 1912), and *Th. nagalandense* Orlov, Dutta, Ghate et Kent, 2006 (vs. large body size, large dorsal asperities, and vomerine teeth present).

Absence of hand webbing, reduced foot webbing, and completely smooth dorsum clearly distinguishes the new species from *Th. horridum* (Boulenger, 1903), *Th. stellatum* Taylor, 1962, *Th. vietnamense* Poyarkov, Orlov, Moiseeva, Pawangkhanant, Ruangsuwan, Vassilieva, Galoyan, Nguyen & Gogoleva, 2015, *Th. ryabovi* Orlov, Dutta, Ghate & Kent, 2006, *Th. phrynoderma* (Ahl, 1927), *Th. asperum* (Boulenger, 1886), and *Th. albopunctatum* (Liu & Hu, 1962) (vs. hand webbing well-developed in *Th. horridum*, rudimentary in remaining taxa; vs. foot webbing complete, dorsum with more or less developed warts and asperities in above-mentioned taxa).

The Malayan species Th. licin and Th. asperum, Indochinese species Th. albopunctatum, and poorly known Th. baibungense (Jiang, Fei & Huang, 2009) and Th. pyaukkya Dever, 2017 can be further distinguished from Theloderma auratum sp. nov. by whitish coloration of whole dorsum or large white blotches on dark dorsal background color (vs. golden-yellow dorsum with golden-orange reticulations and few dark spots in Theloderma auratum sp. nov.), greyish or whitish belly with brown reticulations (vs. whitish to bluish belly with small brown spots and blotches in Theloderma auratum sp. nov.), and uniform red coloration of iris (vs. distinctly bicolored golden/black iris in Theloderma auratum sp. nov.). Furthermore, Th. licin McLeod & Ahmad, 2007 from Sundaland and the Malayan Peninsula can be distinguished from the new species by the uniform dark-red coloration of iris (vs. distinctly bicolored golden/black iris in *Theloderma auratum* sp. nov.) and short rounded snout with ESL/HL ratio below 40% (vs. long pointed snout with ESL/HL ratio over 43% in Theloderma auratum sp. nov.).

Theloderma annae Nguyen, Pham, Nguyen, Ngo & Ziegler, 2016 can be easily differentiated from the new species by a golden-green iris with black reticulations and greenish-grey dorsal pattern (vs. distinctly bicolored golden/black iris and golden-yellow dorsum with golden-orange reticulations in Theloderma auratum sp. nov.) and presence of supernumerary palmar tubercles (vs. absent in Theloderma auratum sp. nov.). Theloderma auratum sp. nov. can be distinguished from two other small-sized Theloderma species found in northern Vietnam and southern China - Th. rhododiscus (Liu & Hu, 1962) and Th. lateriticum Bain, Nguyen & Doan, 2009 - by golden-yellow dorsum with golden-orange reticulations and few dark spots (vs. tea brown to dark grey dorsum in Th. rhododiscus and dorsum with deep brick-red background color with distinct black middorsal spot or blotches in Th. lateriticum), greyish belly or whitish belly with brown reticulations (vs. belly brownish-black scattered with grey-white

network in both taxa), ventral surfaces of disks grey (vs. orange or red in Th. rhododiscus), completely smooth dorsum without asperities or warts (vs. distinctly white dorsal asperities present in both taxa), and distinctly bicolored golden/black iris (vs. uniformly dark reddish brown iris in both taxa). Theloderma lacustrinum Sivongxay, Davankham, Phimmachak, Phoumixay & Stuart, 2016 from Laos can be differentiated from the new species by its uniform red iris (vs. distinctly bicolored golden/black iris), beige-brown upper jaw (vs. uniformly dark reddish-brown upper jaw), and presence of large black blotches in inguinal region (vs. dark inguinal blotches absent).

Theloderma petilum (Stuart & Heatwole, 2004) can be easily differentiated from the new species by two chocolate-brown bands running from lateral surfaces of head toward groin, distinctly separated from brownish-beige dorsum and edged with white (vs. dark lateral bands black to

reddish-brown, sharply contrasting with golden-orange dorsum with golden-orange reticulations in Theloderma auratum sp. nov.).

Superficially, *Theloderma auratum* sp. nov. morphologically resembles other small-bodied Theloderma species found in central and southern Vietnam, namely Th. laeve (Smith, 1924), Th. nebulosum Rowley, Le, Hoang, Dau & Cao, 2011, Th. truongsonense (Orlov & Ho, 2005), and Th. palliatum Rowley, Le, Hoang, Dau & Cao, 2011. Thus, comparisons with these species appear to be the most pertinent: Th. laeve (Smith, 1924), Th. nebulosum Rowley, Le, Hoang, Dau & Cao, 2011, Th. truongsonense (Orlov & Ho, 2005), and Th. palliatum Rowley, Le, Hoang, Dau & Cao, 2011 (Figure 11). Table 6 summarizes the morphometric data on the small-bodied Theloderma species of central and southern Vietnam.

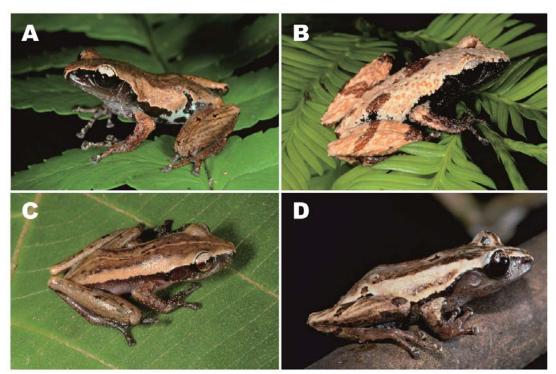

Figure 11 Small-bodied Theloderma species of central and southern Vietnam

A: Th. truongsonense from Kon Ka Kinh N.P., Gia Lai Prov.; B: Th. palliatum from Chu Yang Sin N.P., Dak Lak Prov.; C: Th. laeve from Loc Bac Forestry, Lam Dong Prov.; D: Th. nebulosum from Ngoc Linh Mt., Kon Tum Prov. Photos A-C by Nikolay A. Poyarkov; Photo D by Nikolai L. Orlov.

Theloderma nebulosum (Figure 11D) can be distinguished from the new species by small sparse dorsal asperities present absent), brown dorsum with darker patterning (vs. golden-yellow dorsum with golden-orange reticulations and few dark spots), and dark brown to black ventral surfaces with bluish marbling (vs. whitish to bluish belly with small brown spots and blotches).

Theloderma truongsonense (Figure 11A) from the central and southern Annamite (Truong Son) Mountains can be distinguished from Theloderma auratum sp. nov. by the following morphological attributes: dorsal skin shagreened with numerous small asperities scattered on dorsum and dorsal surfaces of head including upper eyelids (vs. completely smooth dorsum with only few (3-5) flat superciliary tubercles), comparatively shorter snout with rounded snout tip, ESL/SVL tapering snout with pointed tip, ratio below 16% (vs. comparatively longer, ESL/SVL ratio above 17%), dorsum brown with darker patterning (vs. golden-yellow dorsum with golden-orange reticulations and few dark spots), dorsal edge of dark lateral stripe irregular, deep inguinal loop or large black inguinal blotch surrounded by bluish to turquoise edging always present (vs. dark lateral stripe with smooth sharp edge, inguinal loop absent or shallow), comparatively wider and shorter head, HW/HL ratio above 85% (vs. comparatively narrower and longer head, HW/HL ratio below 84%), and comparatively shorter tibia, TL/SVL ratio below 52% (vs. comparatively longer tibia, TL/SVL ratio above 53%).

Theloderma laeve (Figure 11C) from low to mid-elevations of Langbian Plateau, southern Vietnam, can be diagnosed from Theloderma auratum sp. nov. by the following combination of morphological characters: dorsum beige with brownish patterning and thin light middorsal stripe (vs. golden-yellow dorsum with golden-orange reticulations and few dark spots), lateral stripe brownish-violet (vs. black to dark brown lateral stripe), ventral surfaces uniform violet-grey with no dark patterning (vs. whitish to bluish belly with small brown spots and blotches), head short, HL/SVL ratio below 35% (vs. head comparatively longer, HL/SVL ratio over 37%), head width slightly less than head length, HW/HL ratio 86%-93% (vs. head notably longer than wide, HW/HL ratio 78%-84%), comparatively shorter snout with rounded snout tip, ESL/SVL ratio 14%-16% (vs. tapering snout with pointed tip, comparatively longer, ESL/SVL ratio 17%-20%), and comparatively smaller interorbital distance, IOD/SVL ratio 9%-10% (vs. IOD/SVL ratio 11%-14%).

From its sister species, Th. palliatum (Figure 11B), which inhabits high elevations of the Langbian Plateau, Theloderma auratum sp. nov. can be distinguished by the following morphological features: completely smooth dorsum (vs. notably tuberculated dorsum, with dorsal surfaces of body, head, and limbs covered with many tubercles and asperities), golden-yellow dorsum with golden-orange reticulations and few dark spots (vs. beige dorsum with large light-brown blotches on upper eyelids, scapular, and sacral area), dark lateral stripe with smooth sharp edge, inguinal loop shallow or absent, large black inguinal blotch absent (vs. dorsal edge of dark lateral stripe irregular, large black inguinal blotch or dark inguinal loop present), whitish to bluish belly with small brown spots and blotches (vs. almost black belly with thin bluish reticulations), snout dorsally pointed (vs. snout dorsally obtusely rounded), comparatively smaller tympanum, TD/SVL ratio 7%-8% (vs. comparatively larger tympanum, TD/SVL ratio 9%-10%), and comparatively larger eye to nostril distance, END/SVL ratio 11%-13% (END/SVL ratio 9%-10%).

Tadpoles of *Theloderma auratum* **sp. nov.** superficially resemble the tadpoles of *Th. nebulosum* described by Rowley et al. (2011); however, they can be distinguished from the latter by LTRF 5(3–5)/3 (vs. LTRF 4(2–4)/3 in *Th. nebulosum*). Tadpoles of *Th. laeve* and *Th. palliatum* also exhibit LTRF 4(2–4)/3 (see Orlov et al., 2012).

**Etymology**: The specific name "auratum" is a Latin adjective in the nominative singular (neutral gender), derived from Latin "aurum" for "gold", referring to the golden-yellowish dorsal coloration of the new species.

**Recommended vernacular name**: We recommend the following common name in English: Golden Bug-Eyed Frog. Recommended vernacular name in Vietnamese: Éch Cây Sần Vàng.

Conservation status: Theloderma auratum sp. nov. is, to date, known from five localities in the Tay Nguyen Plateau of central Vietnam. Further research is required to estimate its actual distribution, population trends, and possible threats. It appears that the new species is associated with primary undisturbed montane forests and may be affected by growing anthropogenic pressure and forest destruction, as observed in different areas of central Vietnam. Given the available information, we suggest *Theloderma auratum* sp. nov. be tentatively considered as a Data Deficient species following IUCN's Red List categories (IUCN, 2001).

## DISCUSSION

Our phylogenetic data largely confirmed the phylogeny of *Theloderma* as given by Poyarkov et al. (2015), Nguyen et al. (2015), and Sivongxay et al. (2016), but included several taxa not analyzed in these studies. Our data supported subdivision of *Theloderma* into two major clades, corresponding to the subgenera *Stelladerma* (Clade I) and *Theloderma* s. str. (Clade II). Furthermore, *Th. annae* was reconstructed as a sister species of *Th. nebulosum* with high node support, and *Th. moloch*, *Th. phrynoderma*, and *Th. ryabovi* were supported as a monophyletic sister group to the *Th. asperum* complex.

Our research clearly demonstrated that current understanding of the diversity of Theloderma is far from complete. Within Th. asperum, our data strongly suggested paraphyly of Th. pyaukkya from Myanmar with respect to Th. baibungense from the eastern Himalayas. In addition, Th. pyaukkya could be subdivided into two highly divergent non-monophyletic lineages from northern and central Myanmar (P-distance 3.9%). Dever (2017) described Th. pyaukkya without including Th. baibungense in phylogenetic analysis and without examination of Th. baibungense specimens; comparisons of Th. pyaukkya in this paper do not allow the discrimination of Th. pyaukkya from Th. baibungense. Our data indicated that the taxonomic status of Th. pyaukkya lineages requires careful reconsideration: synonymy of this species with Th. baibungense can be assumed; however, high genetic differentiation between its lineages suggests that taxonomic reassessment of this group is necessary. Other examples of high intraspecific genetic distances included Indochinese species Th. lateriticum (P=3.6%), Th. truongsonense (P=3.8%), and Th. albopunctatum (P=2.5%); these results suggest the possible presence of cryptic species in these complexes and incomplete taxonomy of the group. Finally, Theloderma sp. from Gia Lai Province, previously identified as Th. laeve by Nguyen et al. (2015), clearly represented a deeply divergent mtDNA lineage sister to Th. laeve s. str. (P=9.0%) and likely corresponds to a yet undescribed species.

Our study confirmed significant species richness underestimation in Theloderma and reported on a new species of Theloderma from the Tay Nguyen Plateau of the Annamite (Truong Son) Mountains in central Vietnam. This mountainous area harbours the highest diversity of amphibian species in Indochina (Geissler et al., 2015) and is recognized as a local center of herpetofaunal diversity with many new species of amphibians and reptiles described from the plateau in the last decade (Poyarkov et al., 2014, 2017; Rowley et al., 2010, 2011, 2014, 2016; Nguyen et al., 2018, Nguyen et al., in press). Our data indicate that knowledge on amphibian diversity of this area is still far from complete and further diversity is likely to be revealed with additional survey efforts. Habitat loss and modification is a continued threat in the region (Meyfroidt & Lambin, 2008), and is widely recognized as the greatest threat to amphibians in Southeast Asia. Range-restricted species are at greatest risk, and include Theloderma auratum sp. nov., which appears to be a forest specialist restricted to relatively undisturbed broadleaf evergreen montane forests. Further survey efforts and additional taxonomic studies to understand the true diversity of amphibians in the region are urgently required for effective conservation management.

# **COMPETING INTERESTS**

The authors declare that they have no competing interests.

# **AUTHORS' CONTRIBUTIONS**

N.A.P. and N.L.O. designed the study. N.A.P. and I.I.K. collected data. N.A.P. performed molecular experiments. N.A.P. and I.I.K. examined morphology. N.A.P. conducted phylogenetic analyses. S.S.G. conducted acoustic analysis. N.A.P., I.I.K., and S.S.G. wrote the manuscript, N.L.O. revised the manuscript. All authors read and approved the final manuscript.

## **ACKNOWLEDGEMENTS**

Fieldwork was funded by the Joint Russian-Vietnamese Tropical and Technological Center and was conducted under permission of the Department of Forestry, Ministry of Agriculture, and Rural Development of Vietnam (permit numbers 547/TCLN-BTTN, issued 21.04.2016, and 432/TCLN-BTTN, issued 30.03.2017). Forest Protection Departments of the Peoples' Committee of Gia Lai Province provided permits for fieldwork and sample collection (permit numbers 1951/UBND-NV, issued 04.05.2016, and 142/SNgV-VP, issued 11.04.2017). The authors are grateful to Andrey N. Kuznetsov and Leonid P. Korzoun for support and organization of the fieldwork. We are grateful to Valentina Kretova (Moscow) and Alexey A. Evsyunin (Tula Exotarium) for help with preparation of figures for this paper. Many thanks to Evgeniy Popov, Alexander Ostorshabov, Igor V. Palko, Evgeniya N. Solovyeva, and Duong Van Tang for their support during fieldwork and assistance in the laboratory. We are grateful to Evgeny Rybaltovsky and Marina Rybaltovskaya (Zoocom) for their help with animal care. We sincerely thank our Vietnamese colleagues Nguyen Dang Hoi, Hoang Minh Duc, Pham Thi Ha Giang, and Le Xuan Son for help and continued support. For permission to study specimens under their care and permanent support, we thank Valentina F. Orlova (ZMMU) and Natalia B. Ananjeva (ZISP). We are sincerely grateful to Samuel Shonleben and Egill Scallagrimsson for their kind help and useful comments, which helped us improve this manuscript.

## Appendix I

#### List of examined specimens.

Theloderma laeve: ZMMU A-4569 (Bu Gia Map N.P., Binh Phuoc Province, southern Vietnam; 1 male, holotype of Th. bambusicolum); ZMMU A-4570 (Bu Gia Map N.P., Binh Phuoc Province, southern Vietnam; 2 males, paratypes of Th. bambusicolum); ZMMU A-4573 (Bu Gia Map N.P., Binh Phuoc Province, southern Vietnam; 3 females, paratypes of Th. bambusicolum); ZMMU A-4571 (Cat Loc area, Cat Tien N.P., Lam Dong Province, southern Vietnam; 4 males, 1 female, paratypes of Th. bambusicolum):

Theloderma palliatum: ZMMU A-5835 (Chu Yang Sin N.P., Dak Lak Province, southern Vietnam; 4 males);

Theloderma truongsonense: ZMMU A-5827 (SaoLa Reserve, ARoang area, ALuoi district, Thua-Thien - Hue Province, central Vietnam; 5 males);

Theloderma auratum sp. nov.: ZMMU A-5828 (Kon Chu Rang N.R., Gia Lai Province, central Vietnam; 1 male, holotype); ZMMU A-5829 (Kon Chu Rang N.R., Gia Lai Province, central Vietnam; 1 male, paratype); ZMMU A-5830 (Kon Chu Rang N.R., Gia Lai Province, central Vietnam; 1 male, paratype); ZMMU A-5831 (Kon Ka Kinh N.P., Gia Lai Province, central Vietnam; 1 male, paratype); ZMMU A-5832 (Thac Nham Forest, Kon Plong area, Kon Tum Province, central Vietnam; 1 male, paratype); ZMMU A-5833-A-5834 (SaoLa Reserve, ARoang area, ALuoi district, Thua-Thien - Hue Province, central Vietnam; 2 males).
